Basic GIT Commands

Here are some basic GIT commands you need to know:

- **git init** will create a new local GIT repository. The following Git command will create a repository in the current directory:

```
git init
```

- Alternatively, you can create a repository within a new directory by specifying the project name:

```
git init [project name]
```

- **git clone** is used to copy a repository. If the repository lies on a remote server, use:

```
git clone username@host:/path/to/repository
```

- Conversely, run the following basic command to copy a local repository:

```
git clone /path/to/repository
```

- **git add** is used to add files to the staging area. For example, the basic Git following command will index the temp.txt file:

```
git add <temp.txt>
```

- **git commit** will create a snapshot of the changes and save it to the git directory.

```
git commit -m "Message to go with the commit here"
```

- Note that any committed changes won't make their way to the remote repository.

- **git config** can be used to set user-specific configuration values like email, username, file format, and so on. To illustrate, the command for setting up an email will look like this:

```
git config --global user.email youremail@example.com
```

- The -global flag tells GIT that you're going to use that email for all local repositories. If you want to use different emails for different repositories,

- **git status** displays the list of changed files together with the files that are yet to be staged or committed.

```
git status
```

- **git push** is used to send local commits to the master branch of the remote repository. Here's the basic code structure:

```
git push origin <master>
```

- Replace <master> with the branch where you want to push your changes when you're not intending to push to the master branch.

- **git checkout** creates branches and helps you to navigate between them.

For example, the following basic command creates a new branch and automatically switches you to it:

```
command git checkout -b <branch-name>
```

- To switch from one branch to another, simply use:

```
git checkout <branch-name>
```

- **git remote** lets you view all remote repositories. The following command will list all connections along with their URLs:

```
git remote -v
```

- To connect the local repository to a remote server, use the command below:

```
git remote add origin <host-or-remoteURL>
```

- Meanwhile, the following command will delete a connection to a specified remote repository:

```
git remote rm <name-of-the-repository>
```

- **git branch** will list, create, or delete branches. For instance, if you want to list all the branches present in the repository, the command should look like this:

```
git branch
```

- If you want to delete a branch, use:

- **git pull** merges all the changes present in the remote repository to the local working directory.

```
git pull
```

- **git merge** is used to merge a branch into the active one.

```
git merge <branch-name>
```

- **git diff** lists down conflicts. In order to view conflicts against the base file, use

```
git diff --base <file-name>
```

- The following basic command is used to view the conflicts between branches before merging them:

```
git diff <source-branch> <target-branch>
```

- To list down all the present conflicts, use:

```
git diff
```

- **git tag** marks specific commits. Developers usually use it to mark release points like v1.0 and v2.0.

```
git tag <insert-commitID-here>
```

- **git log** is used to see the repository's history by listing certain commit's details. Running the command will get you an output that looks like this:

```
commit 15f4b6c44b3c8344caasdac9e4be13246e21sadw
Author: Alex Hunter <alexh@gmail.com>
Date:   Mon Oct 1 12:56:29 2016 -0600
```

- **git reset** command will reset the index and the working directory to the last git commit's state.

```
git reset --hard HEAD
```

- **git rm** can be used to remove files from the index and the working directory.

```
git rm filename.txt
```

- **git stash** command will temporarily save the changes that are not ready to

- **git show** is a command used to view information about any git object.

```
git show
```

- **git fetch** allows users to fetch all objects from the remote repository that don't currently reside in the local working directory.

```
git fetch origin
```

- **git ls-tree** allows you to view a tree object along with the name, the mode of each item, and the blob's SHA-1 value. Let's say you want to see the HEAD, use:

```
git ls-tree HEAD
```

- **git cat-file** is used to view the type and the size information of a repository object. Use the -p option along with the object's SHA-1 value to view the information of a specific object, for example:

```
git cat-file -p d670460b4b4aece5915caf5c68d12f560a9fe3e4
```

- **git grep** lets users search through committed trees, working directory, and staging area for specific phrases and words. To search for www.hostinger.com in all files, use:

```
git grep "www.hostinger.com"
```

- **gitk** shows the graphical interface for a local repository. Simply run:

```
gitk
```

- **git instaweb** allows you to browse your local repository in the git-web interface. For instance:

```
git instaweb -httpd=webrick
```

- **git gc** will clean unnecessary files and optimize the local repository.

```
git gc
```

- **git archive** lets users create a zip or a tar file containing the constituents of a single repository tree. For instance:

```
git archive --format=tar master
```

- **git prune** deletes objects that don't have any incoming pointers

- **git fsck** performs an integrity check of the git file system and identifies any corrupted objects.

```
git fsck
```

- **git rebase** is used to apply certain changes from one branch to another.

For instance:

```
git rebase master
```
